

Properties of sets of isometries of Gromov hyperbolic spaces

EDUARDO OREGÓN-REYES

Abstract

We prove an inequality concerning isometries of a Gromov hyperbolic metric space, which does not require the space to be proper or geodesic. It involves the joint stable length, a hyperbolic version of the joint spectral radius, and shows that sets of isometries behave like sets of 2×2 real matrices. Among the consequences of the inequality, we obtain the continuity of the joint stable length and an analogue of Berger-Wang theorem.

1 Introduction

Let X be a metric space with distance $d(x, y) = |x - y|$. We assume this space is δ -hyperbolic in the Gromov sense. This concept was introduced in 1987 [13] and has an important role in geometric group theory and negatively curved geometry [6, 13, 15]. There are several equivalent definitions [7], among which the following *four point condition (f.p.c.)* : For all $x, y, s, t \in X$ the following holds:

$$|x - y| + |s - t| \leq \max(|x - s| + |y - t|, |x - t| + |y - s|) + 2\delta. \quad (\text{f.p.c.})$$

This paper deals with isometries of hyperbolic spaces. The first results in this active topic of research assumed X to be geodesic or proper. However, recent works show that the properness condition is irrelevant for many purposes [4, 8, 14, 26]. The Gromov boundary ∂X is a commonly used tool in this study. In this paper, we do not assume X to be geodesic nor proper, and we do not make use of the Gromov boundary, deriving our fundamental results directly from (f.p.c.).

Let us introduce some terminology and notation. Let $Isom(X)$ be the group of isometries of X . For $x \in X$ and $\Sigma \subset Isom(X)$ define

$$|\Sigma|_x = \sup_{f \in \Sigma} |fx - x|.$$

We say that Σ is *bounded* if $|\Sigma|_x < \infty$ for some (and hence any) $x \in X$.

For a single isometry f the *stable length* is defined by

$$d^\infty(f) = \lim_{n \rightarrow \infty} \frac{|f^n x - x|}{n} = \inf_n \frac{|f^n x - x|}{n}.$$

This quantity is well defined and finite by subadditivity and turns to be independent of $x \in X$.

Our first result gives a *lower* bound for the stable length:

Theorem 1.1. *If $x \in X$ and $f \in \text{Isom}(X)$ then:*

$$|f^2(x) - x| \leq |f(x) - x| + d^\infty(f) + 2\delta. \quad (1)$$

For the generalization of the stable length and Theorem 1.1 to bounded sets of isometries, some notation is required. If $\Sigma \subset \text{Isom}(X)$ we denote by Σ^n the set of all compositions of n isometries of Σ . Note that if Σ is bounded then each Σ^n is bounded. We define the *joint stable length* as the quantity

$$\mathfrak{D}(\Sigma) = \lim_{n \rightarrow \infty} \frac{|\Sigma^n|_x}{n} = \inf_n \frac{|\Sigma^n|_x}{n}.$$

Similarly as before, this function is well defined, finite and independent of x . Also, it is useful to define the *stable length* of Σ given by

$$d^\infty(\Sigma) = \sup_{f \in \Sigma} d^\infty(f).$$

With these definitions we are ready to present our main result:

Theorem 1.2. *For every $x \in X$ and every $f, g \in \text{Isom}(X)$ we have:*

$$|fgx - x| \leq \max \left(|fx - x| + d^\infty(g), |gx - x| + d^\infty(f), \frac{|fx - x| + |gx - x| + d^\infty(fg)}{2} \right) + 6\delta. \quad (2)$$

Taking supremum over $f, g \in \Sigma$ and noting that $d^\infty(\Sigma^2) \leq \mathfrak{D}(\Sigma^2) = 2\mathfrak{D}(\Sigma)$ we can obtain a lower bound for the joint stable length similar to Theorem 1.1:

Corollary 1.3. *For every $x \in X$ and every bounded set $\Sigma \subset \text{Isom}(X)$ the following holds:*

$$|\Sigma^2|_x \leq |\Sigma|_x + \frac{d^\infty(\Sigma^2)}{2} + 6\delta \leq |\Sigma|_x + \mathfrak{D}(\Sigma) + 6\delta. \quad (3)$$

Inequalities (1) and (3) are inspired by lower bounds for the spectral radius due to J. Bochi [3, Eq. 1 & Thm. A]. As we will see, the connection between the spectral radius and the stable length will allow us to deduce Bochi's inequalities from (1) and (3) (see Section 2 below), and actually improve them using (2).

We present some applications of Theorems 1.1 and 1.2:

Relation with the joint spectral radius. The joint stable length is inspired by matrix theory. Let $M_d(\mathbb{R})$ be the set of real $d \times d$ matrices and let $\|\cdot\|$ be an operator norm in $M_d(\mathbb{R})$. We denote the spectral radius of a matrix A by $\rho(A)$. The *joint spectral radius* of a bounded set $\mathcal{M} \subset M_d(\mathbb{R})$ is defined by

$$\mathfrak{R}(\mathcal{M}) = \lim_{n \rightarrow \infty} \sup \left\{ \|A_1 \dots A_n\|^{1/n} : A_i \in \mathcal{M} \right\}. \quad (4)$$

Note the similarity with the definition of the joint stable length.

The joint spectral radius was introduced by Rota and Strang [25] and popularized by Daubechies and Lagarias [9]. This quantity has aroused research interest in recent decades and it has appeared in several mathematical contexts (see e.g. [17, 19]).

The relation between the joint spectral radius and joint stable length is made explicit when we consider the hyperbolic plane \mathbb{H}^2 . It is known that $SL_2^\pm(\mathbb{R}) = \{A \in M_2(\mathbb{R}) : \det A = 1\}$ acts on \mathbb{H}^2 by isometries. The homomorphism is given by

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto \tilde{A}z = \begin{cases} \frac{az+b}{cz+d} & \text{if } \det A = 1, \\ \frac{a\bar{z}+b}{c\bar{z}+d} & \text{if } \det A = -1. \end{cases}$$

If $d_{\mathbb{H}^2}$ denote the distance in \mathbb{H}^2 and $\|\cdot\|$ is an operator matrix norm in $M_2(\mathbb{R})$ then we say that

Proposition 1.4. *For every $A \in SL_2^\pm(\mathbb{R})$ and every bounded $\mathcal{M} \subset SL_2^\pm(\mathbb{R})$ we have:*

- i) $d_{\mathbb{H}^2}(\tilde{A}i, i) = 2 \log(\|A\|_2)$.
- ii) $d^\infty(\tilde{A}) = 2 \log(\rho(A))$.
- iii) $\mathfrak{D}(\tilde{\mathcal{M}}) = 2 \log(\mathfrak{R}(\mathcal{M}))$, where $\tilde{\mathcal{M}} = \{\tilde{B} : B \in \mathcal{M}\} \subset Isom(\mathbb{H}^2)$.

(See Section 2 for the proof).

Proposition 1.4 not only allow us to translate hyperbolic quantities to matrix quantities. It also gives matrix versions of Theorems 1.1 and 1.2 and Corollary 1.3, that coincide with particular cases of Bochi's inequalities.

Berger-Wang like theorem. An important result related to the joint spectral radius is the Berger-Wang theorem [1] that says that for all bounded $\mathcal{M} \subset M_d(\mathbb{R})$ we have $\mathfrak{R}(\mathcal{M}) = \limsup_{n \rightarrow \infty} \sup \{\rho(A)^{1/n} : A \in \mathcal{M}^n\}$. From Corollary 1.3 we prove a similar result for the joint stable length in a hyperbolic space.

Theorem 1.5. *Every bounded set $\Sigma \subset Isom(X)$ satisfies*

$$\mathfrak{D}(\Sigma) = \limsup_{n \rightarrow \infty} \frac{d^\infty(\Sigma^n)}{n} = \lim_{n \rightarrow \infty} \frac{d^\infty(\Sigma^{2n})}{2n}.$$

A question that arose from the Berger-Wang theorem is the *finiteness conjecture* proposed by Lagarias and Wang [20] which asserts that for every finite set $\mathcal{M} \subset M_d(\mathbb{R})$ there exists some $n \geq 1$ and $A_1, \dots, A_n \in \mathcal{M}$ such that $\mathfrak{R}(\mathcal{M}) = \rho(A_1 \cdots A_n)^{1/n}$. The failure of this conjecture was proved by Bousch and Mairesse [5].

In the context of sets of isometries, following an idea of I. Morris (personal communication) we refute the finiteness conjecture for $X = \mathbb{H}^2$.

Proposition 1.6. *There exists $\Sigma \subset Isom(\mathbb{H}^2)$ finite such that for all $n \geq 1$*

$$\mathfrak{D}(\Sigma) > \frac{d^\infty(\Sigma^n)}{n}.$$

Let us interpret these facts in terms of Ergodic theory. Given a compact set of matrices \mathcal{M} , the joint spectral radius equals the supremum of the Lyapunov

exponents over all ergodic shift-invariant measures on the space $\mathcal{M}^{\mathbb{N}}$ (see [23] for details.) Therefore, Berger-Wang says that instead of considering all shift-invariant measures, it is sufficient to consider those supported on periodic orbits. A far-reaching extension of this result was obtained by Kalinin [18].

Continuity results. The group $Isom(X)$ possesses a natural topology induced by the product topology on X^X , which is called the *point-open topology*. In this space it coincides with the compact-open topology [8, Prop. 5.1.2]. Using Theorem 1.1 we will prove that the stable length displacement behaves well with respect to this topology:

Theorem 1.7. *The map $f \mapsto d^\infty(f)$ is continuous on $Isom(X)$ with the point-open topology.*

(This result is no longer true for general metric spaces. See Remark 5.3).

As the point-open topology on $SL_2^\pm(\mathbb{R})$ is induced by the Euclidean operator norm, Theorem 1.7 generalizes the known continuity of the spectral radius. The continuity of the joint spectral radius on the space of compact subsets of $M_2(\mathbb{R})$ with respect to the Hausdorff distance is also known. Since in general the space $Isom(X)$ is not metrizable, we need a suitable generalization than the Hausdorff distance.

Let $\mathcal{C}(Isom(X))$ be the set of non empty compact sets of isometries of X with the point-open topology, and we use on this set the *Vietoris topology* [21]. This topology is natural in the sense that its separation, compactness and connectivity properties derive directly from the respective properties on $Isom(X)$ [21, §4]. In fact, when $Isom(X)$ is metrizable the Vietoris topology coincides with the one induced by the Hausdorff distance.

With these notions it is easy to check that every non empty compact set $\Sigma \subset Isom(X)$ is bounded and the joint stable length is well defined. As consequence of Corollary 1.3 we have:

Theorem 1.8. *Endowing $\mathcal{C}(Isom(X))$ with the Vietoris topology the joint stable length $\Sigma \mapsto \mathfrak{D}(\Sigma)$ and the stable length $\Sigma \mapsto d^\infty(\Sigma)$ are continuous.*

Classification of semigroups of isometries. The stable length gives relevant information about isometries in hyperbolic spaces. Recall that for hyperbolic X an isometry $f \in Isom(X)$ is either *elliptic*, *parabolic* or *hyperbolic*. This classification give us a nice use for the stable length [7, Chapter 10, Prop. 6.3] :

Proposition 1.9. *An isometry f of X is hyperbolic if and only if $d^\infty(f) > 0$.*

There also exists a classification for semigroups of isometries in three disjoint families (also called *elliptic*, *parabolic* and *hyperbolic*) obtained by Das, Simmons and Urbanski. An application of Berger-Wang like Theorem 1.5 is the following generalization of Proposition 1.9:

Theorem 1.10. *The semigroup generated by a bounded set $\Sigma \subset Isom(X)$ is hyperbolic if and only if $\mathfrak{D}(\Sigma) > 0$.*

Organization of the paper We will follow this order:

Section 2 is dedicated to the relationship between Theorems 1.1 and 1.2 and matrix theory. Proving these results and applying them in the hyperbolic plane we deduce Bochi's inequalities in dimension 2. Also we prove Berger-Wang theorem for sets of isometries and we give a counterexample to the finiteness conjecture on $Isom(\mathbb{H}^2)$. Then in Section 3 we prove Theorems 1.1 and 1.2. After that, in Section 4 we study the basic properties of the stable lengths, reviewing some known results, and their geometric or dynamical interpretations, specifically on the classification of generated semigroups of isometries on hyperbolic spaces. In Section 5 we study the point-open topology and Vietoris topology on $Isom(X)$ and $\mathcal{C}(Isom(X))$ respectively and we give proofs of the continuity properties of the stable length and the joint stable length. In section 6 we pose some open questions related to the joint stable length. We leave in Section 7 an appendix for the technical results that we used in Section 5, and we prove them for the Vietoris topology of an arbitrary topological group.

2 Motivation: the case of the hyperbolic plane

2.1 Derivation of matrix inequalities

In this section we relate the stable lengths for sets of isometries and the spectral radii for sets of matrices. For that we study the hyperbolic plane.

Let \mathbb{H}^2 be the upper-half plane $\{z \in \mathbb{C} : \text{Im}(z) > 0\}$ endowed with the metric $ds^2 = dz^2 / \text{Im}(z)^2$. This space is log 2-hyperbolic¹. The relation between the distance $d_{\mathbb{H}^2}$ and the Euclidean operator norm $\|\cdot\|_2$ in $M_2(\mathbb{R})$ is established in Proposition 1.4 which we prove now:

Proof of Proposition 1.4. By the definition of the joint stable length and Gelfand's formula $\rho(A) = \lim_{n \rightarrow \infty} (\|A^n\|_2)^{1/n}$ it is easy to see that *ii*) and *iii*) are consequences of *i*).

The proof of *i*) is simple. In the case that \tilde{A} fixes i , that is, A is an orthogonal matrix, the equality is trivial. In the case that A is a diagonal matrix, the proof is a straightforward computation. The general case follows by considering the singular value decomposition. \square

Corollary 2.1. *For every $A \in SL_2^\pm(\mathbb{R})$ and $z \in \mathbb{H}^2$:*

$$d_{\mathbb{H}^2}(\tilde{A}z, z) = 2 \log(\|SAS^{-1}\|_2)$$

where S is any element in $SL_2^\pm(\mathbb{R})$ that satisfies $\tilde{S}z = i$.

Proof. By Proposition 1.4 *i*), $d_{\mathbb{H}^2}(\tilde{A}z, z) = d_{\mathbb{H}^2}(\tilde{A}\tilde{S}^{-1}i, \tilde{S}^{-1}i) = d_{\mathbb{H}^2}(\tilde{S}\tilde{A}\tilde{S}^{-1}i, i) = 2 \log(\|SAS^{-1}\|_2)$, where we used that \tilde{S} is an isometry. \square

Now we present the lower bound for the spectral radius due to Bochi:

¹In fact log 2 is the best possible constant [24, Cor. 5.4].

Proposition 2.2. *Let $d \geq 2$. For every $A \in M_d(\mathbb{R})$ and every operator norm $\|\cdot\|$ in $M_d(\mathbb{R})$:*

$$\|A^d\| \leq (2^d - 1)\rho(A)\|A\|^{d-1}. \quad (5)$$

The generalization of Proposition 2.2 to a lower bound for the joint spectral radius is as follows:

Theorem 2.3 (Bochi). *There exists $C = C(d) > 1$ such that, for every bounded set $\mathcal{M} \subset M_d(\mathbb{R})$ and every operator norm $\|\cdot\|$ in $M_d(\mathbb{R})$:*

$$\sup_{A_i \in \mathcal{M}} \|A_1 \dots A_d\| \leq C\Re(\mathcal{M}) \sup_{A \in \mathcal{M}} \|A\|^{d-1}. \quad (6)$$

Dividing by 2 and applying the exponential function in (1), and using Proposition 1.4 i) and Corollary 2.1 we obtain

$$\|SA^2S^{-1}\|_2 \leq 2\rho(A)\|SAS^{-1}\|_2. \quad (7)$$

If we want to replace $\|\cdot\|_2$ by an arbitrary operator norm we can use the following lemma [3, Lemma 3.2]:

Lemma 2.4. *There exists a constant $C_0 > 1$ such that for every operator norm $\|\cdot\|$ in $M_2(\mathbb{R})$ there exists some S in $SL_2^\pm(\mathbb{R})$ such that for every $A \in M_2(\mathbb{R})$:*

$$C_0^{-1}\|A\| \leq \|SAS^{-1}\|_2 \leq C_0\|A\|.$$

With this lemma we can give another prove to Bochi's Proposition 2.2 for $d = 2$, replacing the constant $(2^2 - 1)$ by $2C_0^2$, where C_0 is the constant given by Lemma 2.4. This involves three steps:

Step 1. The result is valid for all operator norms and $A \in SL_2^\pm(\mathbb{R})$.

Consider the operator norm $\|\cdot\|$ in $M_2(\mathbb{R})$ and the respective $S \in SL_2^\pm(\mathbb{R})$ given by Lemma 2.4. Using this in (7) we obtain

$$\|A^2\| \leq C_0\|SA^2S^{-1}\|_2 \leq 2C_0\rho(A)\|SAS^{-1}\|_2 \leq 2C_0^2\rho(A)\|A\|.$$

Step 2. We extend the result to $A \in GL_2(\mathbb{R})$.

It is easy since inequality (7) is homogeneous in A .

Step 3. We can consider A an arbitrary matrix in $M_2(\mathbb{R})$.

We use that $GL_2(\mathbb{R})$ is dense in $M_2(\mathbb{R})$ considering the metric given by $\|\cdot\|_2$. In this case the matrix multiplication and the spectral radius are continuous functions. So conclusion follows.

If we do the same process to recover Theorem 2.3 in dimension 2 from Theorem 1.2 we will obtain a stronger result:

Proposition 2.5. *For all pairs of matrices $A, B \in M_2(\mathbb{R})$ and all operator norms $\|\cdot\|$ in $M_2(\mathbb{R})$:*

$$\|AB\| \leq 8C_0^2 \max \left(\|A\|\rho(B), \|B\|\rho(A), \sqrt{\|A\|\|B\|\rho(AB)} \right). \quad (8)$$

Proof. The case with $\|\cdot\| = \|\cdot\|_2$ and $A, B \in SL_2^\pm(\mathbb{R})$ is consequence of applying Proposition 1.4 in (2). Steps 1 and 3 are exactly the same as we did before. Step 2 follows noting that (8) is a bihomogeneous inequality, in the sense that when we fix A it is homogeneous in B and when we fix B it is homogeneous in A . \square

2.2 Berger-Wang Theorem for sets of isometries

Now we prove Theorem 1.5. We follow the arguments used in [3, Cor. 1]:

Proof of Theorem 1.5. It is clear that $\mathfrak{D}(\Sigma) \geq \limsup_{n \rightarrow \infty} d^\infty(\Sigma^n)/n$. Fixing a base point x and applying Corollary 1.3 to Σ^n we have

$$|\Sigma^{2n}|_x \leq |\Sigma^n|_x + d^\infty(\Sigma^{2n})/2 + 6\delta.$$

Dividing by n , taking \liminf when $n \rightarrow \infty$ and using that $\mathfrak{D}(\Sigma^2) = 2\mathfrak{D}(\Sigma)$, we obtain the result. \square

As a consequence we can describe the joint stable length of a bounded set of isometries in terms of the joint stable lengths of its finite non empty subsets.

Proposition 2.6. *If X is δ -hyperbolic then for every bounded $\Sigma \subset Isom(X)$*

$$\mathfrak{D}(\Sigma) = \sup \{\mathfrak{D}(B) : B \subset \Sigma \text{ and } B \text{ is finite and non empty}\}.$$

Proof. Let L be the supremum in the right hand side. Clearly $L \leq \mathfrak{D}(\Sigma)$. For the other inequality, let $\epsilon > 0$ and $n \geq 1$ such that $|\mathfrak{D}(\Sigma) - d^\infty(\Sigma^n)/n| < \epsilon/2$. Also let $B = \{f_1, \dots, f_n\} \subset \Sigma$ such that $d^\infty(\Sigma^n) \leq d^\infty(f_1 \cdots f_n) + \epsilon/2$. So we have

$$\begin{aligned} \mathfrak{D}(\Sigma) &\leq d^\infty(\Sigma^n)/n + \epsilon/2 \\ &< d^\infty(f_1 \cdots f_n)/n + \epsilon \\ &\leq \mathfrak{D}(B^n)/n + \epsilon \\ &= \mathfrak{D}(B) + \epsilon. \end{aligned}$$

Then it follows that $\mathfrak{D}(\Sigma) \leq L$. \square

2.3 Finiteness conjecture on $Isom(\mathbb{H}^2)$

We finish this section giving a negative answer to the finiteness conjecture when $X = \mathbb{H}^2$. It is equivalent to find a counterexample to the finiteness conjecture for matrices in $SL_2^\pm(\mathbb{R})$.

The following construction was communicated to us by I.D.Morris:

$$\text{Let } \mathcal{A}^{(t)} = (A_0, A_1^{(t)}) \in SL_2^\pm(\mathbb{R}) \text{ where } A_0^{(t)} = \begin{pmatrix} 2 & 1 \\ 3 & 2 \end{pmatrix}, A_1^{(t)} = \begin{pmatrix} 2t^{-1} & 3t \\ t^{-1} & 2t \end{pmatrix}$$

and $t \in \mathbb{R}^+$. Our claim is the following:

Theorem 2.7. *The family $(\mathcal{A}^{(t)})_{t \geq 1}$ contains a counterexample to the finiteness conjecture.*

Proof. The argument is the similar to the one used in [2]. First, note that for all $t \geq 1$ the set $\mathcal{A}^{(t)}$ satisfies the hypothesis of the Jenkinson-Pollicott's Theorem [16, Thm. 9] and therefore one of the following options holds: either $\mathcal{A}^{(t)}$ is a counterexample to the finiteness conjecture, or there exists a finite product $A_\sigma^{(t)} = A_{i_1}^{(t)} \cdots A_{i_n}^{(t)}$ with $\sigma = (i_1, \dots, i_n) \in \{0, 1\}^n$ not being a power such that $\rho(A_\sigma^{(t)})^{1/n} = \Re(\mathcal{A}^{(t)})$ and, most importantly, the word σ is unique modulo cyclic permutations.

Suppose that no counterexample exists. As the map $t \mapsto \mathcal{A}^{(t)}$ is continuous, by the continuity of the spectral radius and joint spectral radius on $SL_2^\pm(\mathbb{R})$ and $SL_2^\pm(\mathbb{R})$ respectively, the maps $t \mapsto \Re(\mathcal{A}^{(t)})$ and $t \mapsto \rho(A_\sigma^{(t)})$ are continuous for all $\sigma \in \{0, 1\}^n$. So for all σ , the sets $P(\bar{\sigma}) = \left\{ t \in [1, \infty) : \rho(A_\sigma^{(t)})^{1/n} = \Re(\mathcal{A}^{(t)}) \right\}$ are closed in $[1, \infty)$, where $\bar{\sigma}$ denotes the class of σ modulo cyclic permutation.

If the cardinality of $\bar{\sigma}$ such that $P(\bar{\sigma}) \neq \emptyset$ was infinite countable, then the compact connected set $[1, \infty]$ would be partitioned in a countable family of non-empty closed sets, a contradiction (see [10, Thm. 6.1.27]). So, $P(\bar{\sigma})$ is empty for all but a finite number of $\bar{\sigma}$. But by connectedness, it happens that $[1, \infty) = P(\bar{\sigma})$ for a unique class $\bar{\sigma}$. Since $A_1^{(1)}$ is the transpose of $A_0^{(1)}$, the only option is the class of $\sigma = (0, 1) \in \{0, 1\}^2$, but for t large enough we have $\rho(A_\sigma^{(t)})^{1/n} < \Re(\mathcal{A}^{(t)})$, contradiction again. So, for some t_0 , $\mathcal{A}^{(t_0)}$ is a desired counterexample. \square

Remark 2.8. The continuity of the maps $t \mapsto \Re(\mathcal{A}^{(t)})$ and $t \mapsto \rho(A_\sigma^{(t)})$ also follows from the general results proved in Section 5.

Proof of Proposition 1.6. Just take $\Sigma = \tilde{\mathcal{A}}^{(t_0)}$ for t_0 found in Theorem 2.7. \square

3 Proof of Theorems 1.1 and 1.2

We begin with the proof of Theorem 1.1, which is basically using (f.p.c.).

Proof of Theorem 1.1. We follow the arguments in [7, Chapter 9, Lemma 2.2]. Fix x as base point and f isometry. Let $n \geq 2$ be an integer. Using (f.p.c.) on the points x, f^2x, fx and f^nx we obtain:

$$|f^2x - x| + |f^nx - fx| \leq \max(|fx - x| + |f^nx - f^2x|, |f^nx - x| + |f^2x - fx|) + 2\delta.$$

As f is an isometry, if we define $a_n = |f^nx - x|$, the inequality is equivalent to:

$$a_2 + a_{n-1} \leq \max(a_{n-2}, a_n) + a_1 + 2\delta. \quad (9)$$

Now, let $a = a_2 - a_1 - 2\delta$. We need to show that $a \leq d^\infty(f)$. If $a \leq 0$ there is nothing to prove. So, we assume that a is positive. We claim that $a + a_n \leq a_{n+1}$ for all $n \geq 1$, which is clear for $n = 1$. If we suppose it valid for some n , we know from (9):

$$a + a_{n+1} \leq \max(a_{n+2}, a_n).$$

If $a_{n+2} < a_n$, then

$$a_n < a + (a + a_n) \leq a + a_{n+1} \leq a_n$$

a contradiction. Therefore $a + a_{n+1} \leq a_{n+2}$, completing the prof of the claim.

So, by telescoping summation, $na \leq a_n$ for all n , and then

$$a \leq \lim_n \frac{a_n}{n} = d^\infty(f)$$

as we wanted to show. \square

Now we proceed with the proof of Theorem 1.2:

Proof of Theorem 1.2. First we suppose that $\delta > 0$. Let x base point and $f, g \in \text{Isom}(X)$. We use (f.p.c.) on the points x, fgx, fx and f^2x

$$|fgx - x| + |fx - x| \leq \max(|fx - gx| + |fx - x|, |f^2x - x| + |gx - x|) + 2\delta. \quad (10)$$

and we separate into two cases:

$$\text{Case } i) \quad |fx - gx| \leq \max(|fx - x| + d^\infty(g), |gx - x| + d^\infty(f)) + 4\delta:$$

Using this into (10) we obtain

$$\begin{aligned} |fgx - x| &\leq \max(|fx - gx|, |f^2x - x| + |gx - x| - |fx - x|) + 2\delta \quad (\text{by Thm. 1.1}) \\ &\leq \max(|fx - gx|, d^\infty(f) + |gx - x| + 2\delta) + 2\delta \\ &= \max(|fx - gx|, d^\infty(f) + |gx - x| + 2\delta) + 2\delta \quad (\text{by Case } i) \\ &\leq \max(d^\infty(g) + |fx - x|, d^\infty(f) + |gx - x|) + 6\delta \end{aligned}$$

completing the proof of the proposition in this case.

$$\text{Case } ii) \quad |fx - gx| > \max(|fx - x| + d^\infty(g), |gx - x| + d^\infty(f)) + 4\delta:$$

Using this we get

$$|f^2x - x| + |gx - x| \leq |fx - x| + d^\infty(f) + |gx - x| + 2\delta < |fx - x| + |fx - gx| - 2\delta. \quad (11)$$

So, $\max(|fx - x| + |fx - gx|, |f^2x - x| + |gx - x|) = |fx - x| + |fx - gx|$ and we obtain in (10) that

$$|fgx - x| \leq |fx - gx| + 2\delta. \quad (12)$$

Now, we use (f.p.c.) three times. First, on x, fx, fgx and f^2x :

$$|fx - x| + |fx - gx| \leq \max(|fgx - x| + |fx - x|, |f^2x - x| + |gx - x|) + 2\delta.$$

But again by (11), it cannot happen that $|fx - x| + |fx - gx| \leq |f^2x - x| + |gx - x| + 2\delta$, so:

$$|fx - gx| \leq |fgx - x| + 2\delta$$

and combining with (12) we obtain:

$$||fgx - x| - |fx - gx|| \leq 2\delta. \quad (13)$$

As our hypothesis is symmetric in f and g , an analogous reasoning allows us to conclude that

$$||gfx - x| - |fx - gx|| \leq 2\delta. \quad (14)$$

and combining with (13) we obtain

$$||fgx - x| - |gfx - x|| \leq 4\delta. \quad (15)$$

Next, we use (f.p.c.) on x, fgx, fx , and $fgfx$:

$$|fgx - x| + |gfx - x| \leq \max(2|fx - x|, |fgfx - x| + |gx - x|) + 2\delta. \quad (16)$$

But by (15) and assumption ii)

$$|fgx - x| + |gfx - x| \geq 2|fx - gx| - 4\delta > 2(|fx - x| + d^\infty(g) + 4\delta) - 4\delta > 2|fx - x| + 2\delta.$$

So, using this with (15), in (16):

$$2|fgx - x| \leq |fgfx - x| + |gx - x| + 6\delta. \quad (17)$$

Finally, (f.p.c.) on $x, fgfx, fgx, (fg)^2x$ we obtain:

$$|fgfx - x| + |fgx - x| \leq \max(|fgx - x| + |gx - x|, |(fg)^2x - x| + |fx - x|) + 2\delta.$$

If the maximum in the right hand side was $|fgx - x| + |gx - x|$, we would have $|fgfx - x| \leq |gx - x| + 2\delta$. But then by (13) and (14):

$$\begin{aligned} 2|fx - gx| - 4\delta &\leq (|fgx - x| + |gfx - x|) && \text{(by (16))} \\ &\leq \max(2|fx - x|, |fgfx - x| + |gx - x|) + 2\delta \\ &\leq 2\max(|fx - x|, |gx - x|) + 4\delta && \text{(by Case ii)} \\ &< 2|fx - gx| - 4\delta. \end{aligned}$$

This contradiction and Theorem 1.1 applied to fg show us that

$$\begin{aligned} |fgfx - x| &\leq |(fg)^2x - x| + |fx - x| + 2\delta - |fgx - x| \\ &\leq (|fgx - x| + d^\infty(fg) + 2\delta) + |fx - x| + 2\delta - |fgx - x| \\ &\leq |fx - x| + d^\infty(fg) + 4\delta. \end{aligned}$$

Using this with (17) we can finish:

$$\begin{aligned} |fgx - x| &\leq (|fgfx - x| + |gx - x|)/2 + 3\delta \\ &\leq (d^\infty(fg) + |fx - x| + |gx - x|)/2 + 5\delta. \end{aligned}$$

In both cases our claim is true. To conclude the proof, note that a 0-hyperbolic space is δ -hyperbolic for all $\delta > 0$. \square

4 Further properties of the stable length and joint stable length

4.1 Dynamical interpretation and semigroups of isometries

The stable length plays an important role in geometry and group theory (see e.g. [12] and the appendix in [11]). In this section we see its relation with isometries of Gromov hyperbolic spaces.

It is a well known fact that an isometry f of an hyperbolic metric space X belongs to exactly one of the following families:

i) *Elliptic*: If the orbit of some (and hence any) point by f is bounded.

- ii) *Parabolic*: If it is not elliptic and the orbit of some (and hence any) point by f has a unique accumulation point on the Gromov boundary ∂X .
- iii) *Hyperbolic*: If it is not elliptic the orbit of some (and hence any) point by f has exactly two accumulation points on ∂X .

A proof of this classification for general hyperbolic spaces can be found in [8, Thm. 6.1.4], while for proper hyperbolic spaces this result is proved in [7, Chapter 9, Thm. 2.1].

As we said in the introduction, an isometry of X is hyperbolic if and only if its stable length is positive. We want to extend this result for bounded sets of isometries. For our purpose we count with a classification for semigroups of isometries.

A semigroup $G \subset Isom(X)$ is:

- i) *Elliptic*: If Gx is a bounded subset of X for some (hence any) $x \in X$.
- ii) *Parabolic*: If it is not elliptic and there exists a unique point in ∂X fixed by all the elements of G .
- iii) *Hyperbolic*: If it contains some hyperbolic element.

An important result is that these are all the possibilities [8, Thm. 6.2.3] :

Theorem 4.1 (Das-Simmons-Urbanski). *A semigroup $G \subset Isom(X)$ is either elliptic, parabolic or hyperbolic.*

So, as a corollary of Theorem 1.5 we obtain a criterion for hyperbolicity for a certain class of semigroups given by Theorem 1.10, that extends Proposition 1.9. Let Σ be a subset of $Isom(X)$ and denote by $\langle \Sigma \rangle$ the semigroup generated by Σ . That is, $\langle \Sigma \rangle = \cup_{n \geq 1} \Sigma^n$.

Proof of Theorem 1.10. By Theorem 1.5, $\mathfrak{D}(\Sigma) > 0$ if and only if $d^\infty(\Sigma^n) > 0$ for some $n \geq 1$, which is equivalent to $d^\infty(f) > 0$ for some $f \in \cup_{n \geq 1} \Sigma^n = \langle \Sigma \rangle$. This is equivalent to the hyperbolicity of $\langle \Sigma \rangle$ by Proposition 1.9. \square

4.2 Relation with the minimal length

When we require X to be a *geodesic* space (i.e. every pair of points x, y can be joined by an arc isometric to an interval) we have another lower bound for the stable length. If $f \in Isom(X)$ define

$$d(f) = \inf_{x \in X} |fx - x|.$$

This number is called the *minimal length* of f . It is clear that $d^\infty(f) \leq d(f)$. On the other hand we have

Proposition 4.2. *If X is δ -hyperbolic and geodesic and $f \in Isom(X)$ then*

$$d(f) \leq d^\infty(f) + 16\delta.$$

For a proof of this proposition see [7, Chapter 10, Prop. 6.4]. This gives us another lower bound for the joint stable length:

Proposition 4.3. *With the same assumptions of Proposition 4.2, for all bounded $\Sigma \subset \text{Isom}(X)$:*

$$\sup_{f \in \Sigma} d(f) \leq \mathfrak{D}(\Sigma) + 16\delta.$$

Remark 4.4. *A result similar to Proposition 4.2 is false if we do not assume X to be geodesic.*

Indeed, consider X δ -hyperbolic and $f \in \text{Isom}(X)$ with a fixed point and such that $\sup_{x \in X} |fx - x| = \infty$. So, for all $R > 0$ the set $X_R = \{x \in X : |fx - x| \geq R\}$ is a δ -hyperbolic space and f restricts to an isometry f_R of X_R . This is satisfied for example by every non-identity elliptic Möbius transformation in \mathbb{H}^2 . But $d^\infty(f_R) = d^\infty(f) = 0$ and $d(f_R) \geq R$.

This is one of the reasons, together with Proposition 1.9 why we work with a generalization of the stable length instead of the minimal length (elliptic or parabolic isometries can satisfy $d(f) > 0$).

This fact occurs because the bound given for the stable length given by Proposition 4.2 depends on a *convexity* condition. This result is true because δ -hyperbolic geodesic metric spaces are 8δ -convex [7, Chapter 10, Section 5]. In fact, if X is a convex space, for all $f \in \text{Isom}(X)$, $d^\infty(f) = d(f)$ [12, Section 2.6] (this condition is satisfied for example for all complete CAT(0) spaces).

We finish this section showing that the generalizations of the minimum displacement and the stable distance in general may be different. It is the case of \mathbb{H}^2 :

Proposition 4.5. *There exists $\Sigma \subset \text{Isom}(\mathbb{H}^2)$ such that*

$$\mathfrak{D}(\Sigma) < \inf_{z \in \mathbb{H}^2} |\Sigma|_z.$$

where $|\cdot|$ denotes the distance in \mathbb{H}^2 .

Proof. Let $\mathcal{A} = \{F_0, F_1\}$ be a counterexample to the finiteness conjecture given by Theorem 2.7. We will prove that $\Sigma = \tilde{\mathcal{A}}$ satisfies our requirements.

Let $f_i = \tilde{F}_i$ for $i \in \{0, 1\}$. By the construction made in Subsection 2.3, it is a straightforward computation to see that f_0 and f_1 are hyperbolic isometries and that they have disjoint fixed point sets in $\partial\mathbb{H}^2 = \mathbb{R} \cup \{\infty\}$. Hence, by properties of hyperbolic geometry, given $K \geq 0$ the set $C_i(K) = \{z \in \mathbb{H}^2 : |f_i z - z| \leq K\}$ is within bounded distance from the axis of f_i . We conclude that $C_0(K) \cap C_1(K)$ is compact and the map $z \rightarrow |\Sigma|_z = \max(|f_0 z - z|, |f_1 z - z|)$ is proper.

Now suppose that $\mathfrak{D}(\Sigma) = \inf_{z \in \mathbb{H}^2} |\Sigma|_z$ and let $(z_n)_n$ be a sequence in \mathbb{H}^2 such that $|\Sigma|_{z_n} \rightarrow \mathfrak{D}(\Sigma)$. By the properness property the sequence $(z_n)_n$ must be bounded and by compactness we can suppose that it converges to $w \in \mathbb{H}^2$. So by continuity we have $\mathfrak{D}(\Sigma) = |\Sigma|_w$. But then the set \mathcal{A} would have as extremal norm $\|A\| = \|SAS^{-1}\|_2$ where $S \in SL_2^\pm(\mathbb{R})$ satisfies $\tilde{S}w = i$, and by [20, Thm 5.1], \mathcal{A} would satisfy the finiteness property, a contradiction. \square

5 Continuity

5.1 Continuity of the stable length

Now we study the continuity properties of the stable and joint stable lengths. Throughout the section we assume that $Isom(X)$ has the *finite-open topology*. It is generated by the subbasic open sets $\mathcal{G}(x, U) = \{f \in Isom(X) : f(x) \in U\}$ where $x \in X$ and U is open in X , and makes $Isom(X)$ into a topological group [8, Prop. 5.1.3]. The finite-open topology is also called the *pointwise convergence topology* for the following property [10, Prop. 2.6.5]:

Proposition 5.1. *A net $(f_\alpha)_{\alpha \in A} \subset Isom(X)$ converges to f if and only if $(f_\alpha x)_{\alpha \in A}$ converges to fx for all $x \in X$.*

Corollary 5.2. *For all $n \in \mathbb{Z}$ and $x \in X$ the function from $Isom(X)$ to \mathbb{R} that maps f to $|f^n x - x|$ is continuous.*

Proof. As $Isom(X)$ is a topological group, by Proposition 5.1 the function $f \mapsto f^n x$ is continuous for all $x \in X$ and $n \in \mathbb{Z}$. The conclusion follows noting that the map $f \mapsto |f^n x - x|$ is composition of continuous functions. \square

With Corollary 5.2 we can prove Theorem 1.7:

Proof of Theorem 1.7. We follow an idea of Morris (see [22]). By subadditivity, $d^\infty(f)$ is the infimum of continuous functions, hence is upper semi-continuous. For lower semi-continuity, Theorem 1.1 implies that for any $x \in X$:

$$d^\infty(f) = \sup_{n \geq 1} \frac{|f^{2n} x - x| - |f^n x - x| - 2\delta}{n}.$$

So $d^\infty(f)$ is also the supremum of continuous functions. \square

Remark 5.3. *The stable length may be discontinuous if we do not assume that X is δ -hyperbolic.*

Take for example $X = \mathbb{C}$ with the euclidean metric, and let $f_u : \mathbb{C} \rightarrow \mathbb{C}$ be given by $f_u(z) = uz + 1$, where u is a parameter in the unit circle. For $u \neq 1$ we have that f_u is a rotation, and hence $d^\infty(f_u) = 0$. But f_1 is a translation and $d^\infty(f_1) = 1$.

However, the stable length is of course upper semi-continuous for *all* metric spaces.

5.2 Vietoris topology and continuity of the joint stable length

For the continuity of the joint stable length we need to work in the correct space. A natural candidate is $\mathcal{B}(Isom(X))$, the space of non empty bounded sets of $Isom(X)$. Also, let $\mathcal{BF}(Isom(X))$ be the set of closed and bounded subsets of $Isom(X)$. First of all, by the following lemma it is sufficient to consider closed (and bounded) sets of isometries:

Lemma 5.4. *If $\Sigma \in \mathcal{B}(Isom(X))$ then:*

i) $\overline{\Sigma} \in \mathcal{BF}(Isom(X))$.

ii) $|\overline{\Sigma^n}|_x = |\overline{\Sigma}|_x = |\Sigma^n|_x$ for all $x \in X, n \geq 1$.

iii) $\mathfrak{D}(\overline{\Sigma}) = \mathfrak{D}(\Sigma)$.

Proof. Assertion i) is trivial and iii) is immediate from ii). For the latter, let $f \in \overline{\Sigma}$ and f_α a net in Σ converging to f . As $|f_\alpha x - x| \leq |\Sigma|_x$ for all α , then $|f x - x| \leq |\Sigma|_x$. So $|\overline{\Sigma}|_x \leq |\Sigma|_x \leq |\overline{\Sigma}|_x$ and

$$|\overline{\Sigma}|_x = |\Sigma|_x. \quad (18)$$

Now, let $g = f^{(1)} f^{(2)} \dots f^{(n)} \in \overline{\Sigma^n}$ with $f^{(i)} \in \overline{\Sigma}$. There exist nets $(f_\alpha^{(i)})_{\alpha \in A_i}$ such that $f_\alpha^{(i)}$ tends to $f^{(i)}$ for all i . But since $Isom(X)$ is topological group, $f_\alpha = f_{\alpha_1}^{(1)} f_{\alpha_2}^{(2)} \dots f_{\alpha_n}^{(n)}$ (with $\alpha = (\alpha_1, \dots, \alpha_n) \in A_1 \times \dots \times A_n$) defines a net in Σ^n that tends to g . We conclude that $\overline{\Sigma^n} \subset \overline{\Sigma^n}$ and by (18) we obtain

$$|\Sigma^n|_x \leq |\overline{\Sigma^n}|_x \leq |\overline{\Sigma^n}|_x = |\Sigma^n|_x.$$

The conclusion follows. \square

Our next step is to define a topology on $\mathcal{BF}(Isom(X))$. We follow the construction given by E. Michael in [21]. Let $\mathcal{P}(Isom(X))$ the set of non empty subsets of X . If U_1, \dots, U_n are non empty open sets in $Isom(X)$ let

$$\langle U_1, \dots, U_n \rangle := \left\{ E \in \mathcal{P}(Isom(X)) : E \subset \bigcup_i U_i \text{ and } E \cap U_i \neq \emptyset \text{ for all } i \right\}.$$

The *Vietoris topology* on $\mathcal{P}(Isom(X))$ is the one which has as base the collection of sets $\langle U_1, \dots, U_n \rangle$. We say that a subset of $\mathcal{P}(Isom(X))$ with the induced topology also has the Vietoris topology.

With this in mind the space $\mathcal{BF}(Isom(X))$ satisfies one of our requirements:

Proposition 5.5. *For all $x \in X$ the map $\Sigma \mapsto |\Sigma|_x$ is continuous on $\mathcal{BF}(Isom(X))$.*

Proof. It follows from Theorem 1.7 and the fact that taking supremum preserves continuity on $\mathcal{BF}(Isom(X))$, see [21, Prop. 4.7]. \square

For the continuity of the composition map $(\Sigma, \Pi) \mapsto \Sigma\Pi$ we must impose further restrictions. So we work on $\mathcal{C}(Isom(X))$, the set of non empty compact subsets of $Isom(X)$. In this space all our claims are satisfied:

Proof of Theorem 1.8. The idea proof for the continuity of the joint stable length is the same one that we used in the proof of Theorem 1.7. We claim that in $\mathcal{C}(Isom(X))$ the maps $\Sigma \mapsto |\Sigma|_x$ and $\Sigma \mapsto \Sigma^n$ are continuous for all $x \in X$ and $n \in \mathbb{Z}^+$. The first assertion is Proposition 5.5 and the second one comes from a general result in topological groups. We prove it in the Section 7 (see Corollary 7.3). Similarly the continuity of the stable length follows as in the proof of Proposition 5.5. \square

It follows from Theorem 1.8 that the joint stable length is continuous on the set of non empty finite subsets of $Isom(X)$. This affirmation together with Proposition 2.6 allows us to conclude a semi-continuity result on $\mathcal{BF}(Isom(X))$:

Theorem 5.6. *The map $\mathfrak{D}(\cdot) : \mathcal{BF}(Isom(X)) \rightarrow \mathbb{R}$ is lower semi-continuous.*

Proof. Let $\epsilon > 0$ and $\Sigma \in \mathcal{BF}(Isom(X))$. By Proposition 2.6 there is $B \subset \Sigma$ finite with $\mathfrak{D}(\Sigma) - \mathfrak{D}(B) < \epsilon/2$. As $B \in \mathcal{C}(Isom(X))$, by Theorem 1.8 there exist open sets $U_1, \dots, U_n \subset Isom(X)$ such that $V = \langle U_1, \dots, U_n \rangle$ is an open neighborhood of B and if F is finite and $F \in V$ then $|\mathfrak{D}(B) - \mathfrak{D}(F)| < \epsilon/2$.

Let $W = \langle Isom(X), U_1, \dots, U_n \rangle$. Clearly W is an open neighborhood of Σ , and if $A \in W$, then there exist f_1, \dots, f_n with $f_i \in A \cap U_i$ for all i . So $C = \{f_1, \dots, f_n\} \in V$ and then $|\mathfrak{D}(B) - \mathfrak{D}(C)| < \epsilon/2$. We have

$$\mathfrak{D}(\Sigma) < \mathfrak{D}(B) + \epsilon/2 < \mathfrak{D}(C) + \epsilon \leq \mathfrak{D}(A) + \epsilon$$

and the conclusion follows. \square

6 Questions

In this section we pose some questions related to the results we have obtained.

6.1 Lower bound for the j.s.l. in geodesic spaces

Is it true that for a δ -hyperbolic geodesic space X there exists a real constant $C = C(X)$ such that for all bounded $\Sigma \subset Isom(X)$ we have

$$\inf_{x \in X} |\Sigma|_x \leq \mathfrak{D}(\Sigma) + C?$$

This result would be a better generalization of Proposition 4.2 than Proposition 4.3.

Using Lemma 2.4 and the equality $\mathfrak{R}(\mathcal{M}) = \inf_{\|\cdot\|} \sup \{\|A\| : A \in \mathcal{M}\}$ valid for every bounded $\mathcal{M} \subset M_2(\mathbb{R})$ (see [25, Prop. 1]), it is easy to see that \mathbb{H}^2 satisfy this condition with $C = 2 \log C_0$. By the discussion from Subsection 4.2 one may expect it to be true if X is a δ -convex space.

6.2 Continuity on $\mathcal{BF}(Isom(X))$

If X is hyperbolic but not proper, is the joint continuous on $\mathcal{BF}(Isom(X))$? A natural candidate to test continuity is the infinite dimensional hyperbolic space \mathbb{H}^∞ (see [8, Part 1.2]).

6.3 Related inequalities on other kinds of spaces

What happens when we relax the curvature conditions? Do modified versions of inequality (3) hold? Motivated by the matrix inequality (6), the following inequality seems a natural candidate:

$$|\Sigma^d|_x \leq (d-1)|\Sigma|_x + \mathfrak{D}(\Sigma) + C, \quad (19)$$

where the constants C and d depend only on X but not on the point x and the bounded set Σ .

For the purpose of applications as those obtained in this paper, such an inequality would be sufficient.

Let us see that for euclidean spaces, all such inequalities fail:

Proposition 6.1. *If $n \geq 2$, \mathbb{R}^n does not satisfy inequality (19) for any $d \geq 2$ and $C > 0$.*

Proof. First consider $n = 2$, that is $X = \mathbb{C}$. Suppose that for some d and C inequality (19) holds. Fix $x = 0$ and consider the isometries $f_{u,a}(z) = uz + a$, where $|u|=1$ and we choose $|a| > C$. Then for $u \neq 1$, by (19) we have

$$|u^{d-1}a + u^d a + \cdots + ua| \leq (d-1)|ua| + C.$$

Taking limit when $u \rightarrow 1$ we obtain $d|a| \leq (d-1)|a| + C$, contradicting the choice of a and concluding the proof in this case. In the case of \mathbb{R}^n with $n > 2$, the same example multiplied by the identity works. \square

In particular, Proposition 6.1 shows that (19) fails for CAT(0) spaces, at least without further hypothesis. We ask if there are natural classes of metric spaces for which inequality (19) holds.

7 Appendix: Vietoris topology over topological groups

This section is dedicated to the topological results that we used in Section 5. We assume that X is a Hausdorff topological space and we let $\mathcal{P}(X)$ be the set of non empty subsets of X endowed with the Vietoris topology defined in Section 5. Also let $\mathcal{C}(X)$ be the set of non empty compact subsets of X .

The following theorem is a criterion for convergence of nets in $\mathcal{P}(X)$ when the limit is compact. We need some notation: If A, B are directed sets, the notation $B \prec_h A$ means that $h : B \rightarrow A$ is a function satisfying the following condition: for all $\alpha \in A$ there is some $\beta \in B$ such that $\gamma \geq \beta$ implies $h(\gamma) \geq \alpha$. We say that a net $(x_{h(\beta)})_{\beta \in B}$ is a *subnet* of the net $(x_\alpha)_{\alpha \in A}$ if $B \prec_h A$. For our purposes the criterion is as follows:

Theorem 7.1. *A net $(\Sigma_\alpha)_{\alpha \in A} \subset \mathcal{P}(X)$ converges to $\Sigma \in \mathcal{C}(X)$ if and only if both conditions below hold:*

- i) *For every $f \in \Sigma$ and every U open containing f there exists $\alpha \in A$ such that $\beta \geq \alpha$ implies $\Sigma_\beta \cap U \neq \emptyset$.*
- ii) *Every net $(f_{h(\beta)})_{\beta \in B}$ with $B \prec_h A$ and $f_{h(\beta)} \in \Sigma_{h(\beta)}$ has a convergent subnet $(f_{h \circ k(\gamma)})_{\gamma \in C}$ with $C \prec_k B$ and with limit in Σ .*

This result is perhaps known, but in the lack of an exact reference we provide a proof (compare with [6, Chapter I.5, Lemma 5.32]).

Proof. We first prove the “if” part:

Let $\langle U_1, \dots, U_n \rangle$ a basic open containing Σ . We must show that for some $\alpha \in A$, if $\beta \geq \alpha$ then $\Sigma_\beta \subset \bigcup_{1 \leq i \leq n} U_i$ and $\Sigma_\beta \cap U_i \neq \emptyset$ for all i .

Suppose that our first claim is false. Then for all $\alpha \in A$ there exists $h(\alpha) \geq \alpha$ such that $\Sigma_{h(\alpha)} \not\subset \bigcup_{1 \leq i \leq n} U_i$. Then, for all α there exists $f_{h(\alpha)} \in \Sigma_{h(\alpha)}$ such that $f_{h(\alpha)} \notin U_i$ for all i . Defining $B = \{h(\alpha) : \alpha \in A\}$, the set $\{f_{h(\alpha)}\}_{\alpha \in A}$ is a net with $A \prec_h A$. Hence since we are assuming *ii*), it has a convergent subnet $(f_{h(k(\gamma))})_{\gamma \in C}$ with limit $f \in \Sigma$ and $C \prec_k A$. But $f \in U_j$ for some j and there is a $\gamma \in C$ with $f_{h(k(\gamma))} \in U_j$, contradicting the definition of $h(k(\gamma))$. So there exists α_0 such that $\beta \geq \alpha_0$ implies $\Sigma_\beta \cap U \neq \emptyset$.

Now, fix $j \in \{1, \dots, n\}$ and suppose that for all α , $\Sigma_{\beta(\alpha)} \cap U_j = \emptyset$ for some $\beta(\alpha) \geq \alpha$. Noting that $\langle U_j, X \rangle$ also contains Σ , there exists α such that $\Sigma_\beta \cap U_j \neq \emptyset$ for $\beta \geq \alpha$, contradicting the existence of $\Sigma_{\beta(\alpha)}$. So for all j , there is some α_j such that $\Sigma_\beta \cap U_j \neq \emptyset$. Finally, any $\alpha \geq \alpha_j$ for $0 \leq j \leq n$ satisfied our requirements.

For the converse, suppose that Σ_α tends to Σ . Let $f \in \Sigma$ and U be an open neighborhood of f . The set $\langle U, X \rangle$ is open and contains Σ . So there exists some α such that for all $\beta \geq \alpha$, $\Sigma_\beta \in \langle U, X \rangle$ and hence $\Sigma_\beta \cap U \neq \emptyset$.

Finally, let $(f_{h(\beta)})_{\beta \in B}$ be a net with $B \prec_h A$ and $f_h(\beta) \in \Sigma_{h(\beta)}$. We claim that this net has a subnet converging to an element of Σ . For $\beta \in B$ consider the set $E(\beta) = \{f_{h(\gamma)} : \gamma \in B \text{ and } \gamma \geq \beta\}$ and let $F(\beta) = \overline{E(\beta)}$.

If $\bigcap_{\beta \in B} F(\beta) \cap \Sigma = \emptyset$, the collection $\{X \setminus F(\beta)\}_{\beta \in B}$ is an open cover of Σ and by compactness it has a minimal finite subcover $\{X \setminus F(\beta_i)\}_{1 \leq i \leq m}$. This implies that $\Sigma \in \langle X \setminus F(\beta_i) \rangle_{1 \leq i \leq m}$ and by our convergence assumption, for some $\alpha_0 \in A$ it happens that $\Sigma_\alpha \subset \bigcup_{1 \leq i \leq m} X \setminus F(\beta_i)$ when $\alpha \geq \alpha_0$. But $B \prec_h A$, so if we take $\beta_0 \in B$ such that $h(\beta_0) \geq \alpha_0$ and β' greater than β_i for all $0 \leq i \leq m$, then $f_{h(\beta')} \notin F(\beta_i)$ for some i . This contradicts that $f_{h(\beta')} \in E(\beta_i) \subset F(\beta_i)$. So there exists some $f \in \bigcap_{\beta \in B} F(\beta) \cap \Sigma$.

Then for every open neighborhood U of f and every $\beta \in B$, there exists a $f_{h \circ k(U, \beta)} \in U \cap E(\beta)$ (this implies that $k(U, \beta) \geq \beta$). Let \mathcal{N} be the set of open neighborhoods of f partially ordered by reverse inclusion. In this way $\mathcal{N} \times B$ with the product order becomes a directed set. Now consider the map $k : \mathcal{N} \times B \rightarrow B$ and let $\beta \in B$. For some $U_0 \in \mathcal{N}$, every $(V, \gamma) \in \mathcal{N} \times B$ with $(V, \gamma) \geq (U_0, \beta)$ satisfies $k(V, \gamma) \geq \gamma \geq \beta$. So $\mathcal{N} \times B \prec_k B$ and $(f_{h \circ k(\gamma)})_{\gamma \in \mathcal{N} \times B}$ is a subnet of $(f_{h(\beta)})_{\beta \in B}$. To finish the proof we must verify that f is limit to this subnet. So, let $U \in \mathcal{N}$. For $(U, \beta) \in \mathcal{N} \times B$ we have that $(V, \gamma) \geq (U_0, \beta)$ implies $f_{h \circ k(V, \gamma)} \in V \cap E(\gamma) \subset U$. So f is our desired limit and our claim is proved. \square

As application to Theorem 7.1 let G be a Hausdorff topological group with identity e . If $o : G \times G \rightarrow G$ is the composition map and $\Sigma, \Pi \in \mathcal{C}(G)$ then $\Sigma\Pi = o(\Sigma \times \Pi) \in \mathcal{C}(G)$, so it induces a composition map $\pi : \mathcal{C}(G) \times \mathcal{C}(G) \rightarrow \mathcal{C}(G)$. We establish that this map is continuous.

Theorem 7.2. *The composition map $\pi : \mathcal{C}(G) \times \mathcal{C}(G) \rightarrow \mathcal{C}(G)$ given by $\pi(\Sigma, \Pi) = \Sigma\Pi$ is continuous.*

Proof. Let $(\Sigma_\alpha, \Pi_\alpha)_{\alpha \in A}$ a net that converges to (Σ, Π) . We claim that $(\Sigma_\alpha \Pi_\alpha)_{\alpha \in A}$ tends to $\Sigma\Pi$. For that, we use the equivalence given by Theorem 7.1. Let $f \in \Sigma$,

$g \in \Pi$ and U an open neighborhood of fg . So $f^{-1}Ug^{-1}$ is an open neighborhood of e and hence there exists V open with $e \in V^2 \subset f^{-1}Ug^{-1}$. Then we have $f \in fV$ and $g \in Vg$.

So there exists α_1 and α_2 such that $\beta \geq \alpha_1$ implies $\Sigma_\beta \cap fV \neq \emptyset$ and $\beta \geq \alpha_2$ implies $\Sigma_\beta \cap Vg \neq \emptyset$. If we take α_0 greater than α_1 and α_2 , for $\beta \geq \alpha_0$ there exists $f_\beta \in \Sigma_\beta$ and $g_\beta \in \Sigma_\beta$ such that $f_\beta \in fV$ and $g_\beta \in Vg$. We conclude that for all $\beta \geq \alpha_0$, $f_\beta g_\beta \in fV^2g \subset U$, hence $\Sigma_\beta \Pi_\beta \cap U \neq \emptyset$ for all $\beta \geq \alpha_0$.

Now, let $B \prec_h A$ such that $(f_{h(\beta)}g_{h(\beta)})_{\beta \in B}$ is a net with $f_{h(\beta)} \in \Sigma_{h(\beta)}$ and $g_{h(\beta)} \in \Pi_{h(\beta)}$. We must exhibit a subnet convergent to an element in $\Sigma\Pi$. But it is easy. Since $\Sigma_{h(\beta)} \rightarrow \Sigma$, there exists $C \prec_k B$ such that $(f_{h \circ k(\gamma)})_{\gamma \in C}$ is a net that tends to $f \in \Sigma$. Also, as $C \prec_{h \circ k} A$ there exists $D \prec_l C$ with $(g_{h \circ k \circ l(\lambda)})_{\lambda \in D}$ is a net and converges to $g \in \Pi$. Then $(f_{h \circ k \circ l(\lambda)}g_{h \circ k \circ l(\lambda)})_{\lambda \in D}$ tends to $fg \in \Sigma\Pi$. Our proof is complete. \square

Corollary 7.3. *The map $\Sigma \mapsto \Sigma^n$ is continuous in $\mathcal{C}(G)$ for all $n \in \mathbb{Z}^+$.*

Acknowledgment I am grateful to my advisor J. Bochi for very valuable discussions and corrections throughout all this work. I also thank to I. Morris for communicating us the counterexample given in Theorem 2.3, and helping in the proofs of Theorem 1.7 and Proposition 4.5. This article was supported by FONDECYT project 1140202 and by the Center of Dynamical Systems and Related Fields código ACT1103.
